
Measure realized work per round

D_{real}	Draft through its actual state interface
R_{target}	Complete target-side round work
X	Residual cost, without double counting
C	All output tokens committed per round

$$S = C / (D_{\text{real}} + R_{\text{target}} + X)$$

Costs normalized by T_b; one consistent boundary.

Separate proxy: V_k^{micro} is not complete R_{target}.
